PROBLEM DOMAIN: NUMBER THEORY

-APPLICATION DOMAIN: CRYPTOGRAPHY

**- PUBLIC KEY ENCRYPTION : RSA
DESIGN AND CORRECTNESS**

Design of an Encryption Algorithm

- Requirement: A -----M-----> B
- Protocol outline:
 - Let $E(M) = M^k \pmod{n}$ for some +ve integers n and k
 - A sends $M' = E(M)$ to B
 - B receives M'
 - B computes $E^{-1}(M') = (M')^{k'} \pmod{n}$ for some +ve integer k'

Design of an Encryption Algorithm

- Requirement: $A \text{ -----} M \text{ -----} \rightarrow B$
- Protocol outline:
 - Let $E(M) = M^k \pmod{n}$ for some +ve integers n and k
 - A sends $M' = E(M)$ to B
 - B receives M'
 - B computes $E^{-1}(M') = (M')^{k'} \pmod{n}$ for some +ve integer k'
- This requires that
 - $M^{k*k'} = M \pmod{n}$

Decryption Key – Requirements

- For ensuring $M^{k*k'} = M \pmod n$:
 - we can leverage Euler's Theorem: i.e.
 - if $k*k' = 1 + j*\phi(n)$ for some +ve integer j
 - then $M^{k*k'} = M^{1+j*\phi(n)} = M \pmod n$
- Suppose we can ensure that
 - $M^{k*k'} = M^{1+j*\phi(n)}$
- There is still a catch!

This is true only for M in Z_n^ !!*

Ensuring Decryption Works – for M in Z_n^*

- For ensuring $M^{k*k'} = M \pmod n$:
 - if $k*k' = 1 + j*\phi(n)$ for some +ve integer j
 - then $M^{k*k'} = M^{1+j*\phi(n)} = M \pmod n$by Euler's Theorem: i.e.
- For ensuring $k*k' = 1 + j*\phi(n)$ for some +ve integer j :
- choose k in $Z_{\phi(n)}^*$ and let k' be inverse of k in $(Z_{\phi(n)}^*, *_{\phi(n)})$
 - Then $k*k' = 1 \pmod{\phi(n)}$
 - i.e. $k*k' = 1 + j*\phi(n)$
 - Note that
 - Inverse of k in $(Z_n^*, *n)$ can be computed in polynomial time given n and k (by Aryabhatiya's algorithm)

Design of a Public Key Encryption Algorithm

RECAP:

- We have: for M in Z_n^*
 - $M^{1+j*\phi(n)} = M \pmod n$
- and by choosing k in $Z_{\phi(n)}^*$ and k' as the inverse of k in $(Z_{\phi(n)}^*, *_{\phi(n)})$, we have
 - $M^{k*k'} = M^{1+j*\phi(n)} = M \pmod n$

Generalization

- By choosing $n = p * q$ for primes p and q , for any M in Z_n
 - we claim $M^{1+j*\phi(n)} = M \pmod n$ (see Lemma next slide)
 - and thus $M^{k*k'} = M^{1+j*\phi(n)} = M \pmod n$.

Ensuring Decryption Works for any message

- Lemma:

- Assuming $n = p * q$ for primes p and q , $M^{1+j*\phi(n)} = M \pmod{n}$ for M in \mathbb{Z}_n

- Proof:

- If $n = p * q$, then $\gcd(M, n)$ must be 1 or p or q .
 - if $\gcd(M, n) = 1$ then $M^{1+j*\phi(n)} = M \pmod{n}$ [by E.T.]
 - if $\gcd(M, n) = p$ then
 - $M^{1+j*\phi(n)} = M = 0 \pmod{p}$ [by assumption]
 - $M^{1+j*\phi(n)} = M^{1+j*\phi(p)*\phi(q)} = M \pmod{q}$ [by E.T.]
 - and therefore $M^{1+j*\phi(n)} = M \pmod{pq}$ [since $\gcd(p, q) = 1$]
 - if $\gcd(M, n) = q$ then $M^{1+j*\phi(n)} = M \pmod{pq}$ similarly.

Encryption Algorithm - RSA

- RSA-Protocol Outline:
 - Let $E(M) = M^k \pmod{n}$ for some $n = p * q$ where p and q are primes and some k in $Z_{\phi(n)}^*$
 - A sends $M' = E(M)$ to B
 - B receives M'
 - B computes $E^{-1}(M') = (M')^{k'} \pmod{n}$ where k' is the inverse of k in $(Z_{\phi(n)}^*, * \phi(n))$
- Communication Correctness:
 - *(see previous slides)* $E^{-1}(E(M)) = M$
- Communication Efficiency:
 - Exponentiation modulo n can be computed in polynomial time
